

End-to-End Prototype we discussed

1. **The source material needs collecting.** To do so, use [the Webrecorder browser extension](#): go to [the Densho DR collection](#), start an “archiving session” and click on [each individual page](#) you want to record, in order. There is about 23 individual photos we want to make sure we capture. End the recording session. You can then download [a WACZ file](#) from the extension, probably weighing 10s-100sMBs.
2. We need to **extract the “original” photos from the web archive created above**. With the WACZ file on your file system, get yourself a Claude Code and get it to find the 23-24 photos we’re most interested in. Save these photos on the filesystem next to the WACZ file.
3. **Let’s ingest this material in the Starling database** we set up for the class. Put the WACZ file and the photographs thus created in a Google Drive, and share that link with Basile <basile@starlinglab.org>. Basile will need to copy them over to the Class Drive...
He will give you a table/spreadsheet, with 24 rows, one per item: the WACZ and the photos.

Asset CID	Asset original name	group_subcollection
-----------	---------------------	---------------------

4. Meanwhile, you will **learn how to interact with the Starling SDK and CLI**. [Clone this repo](#) locally, and start a Claude Code instance to explore its docs and codebase. Questions you’re interested in:
 - a. How do I compute an IPFS CID with the Starling CLI?
 - b. How do I perform cryptographic registrations of an asset or group of assets?
FYI notice how only [some of the Attributes of this Asset](#) are showing as “registered on Cardano”
 - c. How do I represent relationships between assets in AA, and what are my options?
 - d. For an asset stored in the system, how do I export a C2PA-stamped version of it, which encodes some of its Authenticated Attributes? Etc.

5. Design phase:

- a. **On the C2PA manifests**, the recommendation is to start with designing visually what you want to show in your webapp, and walk backwards from there to design the appropriate C2PA manifests. Use Claude Code so data structures don't get too much in your way. There's no right and wrong in designing an interface – it should show how you think of trust signals.
- b. **On creating relationships**, speaking with Basile again or sharing a visual plan would be really helpful. What are you trying to represent? Remember [Basile's Week 7 slides](#): how you model knowledge is actually quite personal, and Basile can support.

6. Once we've got ingest (3) done by the Starling team, a plan for our relationships (5), and some level of familiarity with the CLI (4), it's time to get cracking. **You'll `ssh` into the class server we've set up and execute your plan.**

```
$ ssh sysadmin@64.23.243.235
```

At the end, we'll have C2PA-stamped photos you've exported back to your computer, and which you can use in your webapp for the hotspots.

7. **Stretch goal**, optional: Critical interrogation phase:

- a. **Design a Claude Skill which will interrogate and verify your assets.** There again, there is no right and wrong. To design your prompt, we recommend working backwards from what you want the results to be.
The Starling team is very happy to support and experiment hand-in-hand here. We can pull in review from Guardian Project's Nathan – see [his skill about C2PA data for Proofmode bundles](#).
